

Agency as a Bookkeeping Projection

Amos Jay Maley

Abstract

Agency is widely treated as a foundational explanatory property across domains. This paper shows that agency is not a standing-supported invariant but a bookkeeping projection. Under standing-closed admissibility, agency introduces no admissible discriminator and fails redescription stability. Elimination by closure therefore applies.

1 Introduction

Agency persists as an intuitive explanatory construct. Under standing closure, it does not survive as foundational.

2 Standing-Closed Admissibility

Standing closure prevents illicit primitive injection across domains.

3 Redescription Stability

Agency does not partition admissible equivalence classes.

4 Why Agency Persists

Agency is cognitively efficient but not ontically real.

5 Elimination by Closure

If a construct introduces no standing-supported discriminator, it is eliminable.

6 Governance Consequences

Removing agency restores mechanical accountability and scope-based control.

7 Conclusion

Agency is a descriptive convenience, not an admissible primitive.
